

PORTABLE TRUST

From Digital Product Passports to Creator Rights

Art as the first use case. Trust infrastructure as the larger opportunity.

Felipe Gustavo Santana dos Santos

Ethereum Builders Tour / EAG Global Buildathon x LabSEC / 2026

Research thesis, identity experiment, rights-management field notes and hackathon proposal

Author: @w3bgus.eth / Felipe Gustavo Santana dos Santos / Felipe Gusta | Accelerator: MeGust4 Networks | Incubator: T0FU TURE |
Research location: São Paulo | Hackathon location: Florianópolis

Document version: updated 12 August 2026 · 08:20 BRT (Brasília time)

BUILDATHON EDITION

Florianópolis, Brazil | Saturday, 12 September 2026 | 08:00-18:30 | InPETU hub / UFSC

Author participation for this edition: remote research and product guidance for LabSEC builders. The author is not physically present at the venue.

Privacy note: personal and biometric information visible in field-research photographs has been intentionally blurred for publication.

0. Buildathon context and proposed challenge

The EAG Global Buildathon in Florianópolis is a full-day prototyping event for Ethereum-native applications. The official event page lists tracks including AI-Native Creator Economy & Digital Rights, Local AI / Private AI / User-Owned Data, smart devices and real-world Ethereum applications. LabSEC is listed among the supporting organizations, making trust architecture, identity, signatures and privacy a natural contribution from the UFSC security community.

Field	Buildathon data
Event	EAG Global Buildathon - Florianópolis, Brazil
Date / time	12 September 2026 (Saturday), 08:00-18:30
Venue	Centro de Inovação, Pesquisa, Empreendedorismo e Tecnologia da UFSC (InPETU hub)
Address	Av. Luiz Boiteux Piazza, 1380-1984 - Canasvieiras, Florianópolis - SC, 88054-700, Brazil
Relevant track	AI-Native Creator Economy & Digital Rights
Local context	ETH Floripa / blockful / Infinity Base, with support from LabSEC, InPETU hub, UFSC and ecosystem partners

Official format: check-in from 08:00; prototype building and workshops through the day; submissions close at 15:00; three-minute project presentations plus Q&A run from 15:00; winner announcement is scheduled for 18:30.

PROPOSED HACK CHALLENGE

Como uma obra física consegue carregar sua história verificável entre artista, galeria e compradores, sem depender de uma plataforma central como autoridade?

English framing: How can a physical artwork carry its verifiable history across artist, gallery and buyers without depending on a single platform as the authority?

1. Thesis

A work of art does not stop existing after its first sale. It moves through a lifecycle: CREATE -> AUTHENTICATE -> EXHIBIT -> SELL -> TRANSFER -> RESELL -> LICENSE -> REPRODUCE.

Yet the evidence associated with this lifecycle is fragmented across artists, galleries, collectors, rights-management organizations, brands, contracts, certificates, marketplaces and private databases.

CORE HYPOTHESIS

Creators and artworks should be able to carry their verifiable history across organizations and platforms.

We call this principle Portable Trust: trust that can move across platforms and institutions without losing its issuer, context, evidence or verifiability.

2. Why this matters now

The global art market returned to growth in 2025. Art Basel and UBS estimate USD 59.6 billion in global sales, 41.5 million transactions and 9% growth in public auction sales. The US, UK and China represented 76% of global sales by value. The market is international, high-value and dependent on repeated transfers of unique assets.

Signal	2025 figure
Global art sales	USD 59.6B
Transactions	41.5M
Public auction sales growth	+9% YoY
US + UK + China share	76%

The opportunity is not simply to tokenize art. It is to build infrastructure capable of following the economic and rights lifecycle of the artwork.

3. Two creator-economy problems

3.1 Secondary-market visibility and resale rights

An artist may sell an artwork for R\$5,000, see it resold later for R\$30,000 and again for R\$150,000, and never receive reliable information about those transactions. Brazil recognizes an Artist's Resale Right (direito de sequência): Article 38 of Law 9.610/1998 gives the author an inalienable and irrevocable right to at least 5% of the verifiable price increase in each qualifying resale of an original artwork or manuscript.

TECHNOLOGY BOUNDARY

The protocol should not decide by itself whether a payment is legally due. It should make lifecycle events observable, attributable and verifiable, then route the event to the relevant rights and legal process.

3.2 Commercial licensing and underpricing

A mural commissioned for R\$15,000 may look like one deliverable while the agreement can include photography, social media, video, advertising, paid media, merchandise, global reproduction, derivative works and long-term usage rights. The artist may be pricing one deliverable while licensing several rights.

An AI Rights Agent can convert contract language into structured rights - territory, duration, channels, reproduction, derivatives and commercial uses - and flag what is being granted. Its role is to make rights visible and auditable, not to replace lawyers or collective-rights organizations.

4. Field research update: AUTVIS and the existing rights network

A conversation with AUTVIS changed the framing of this research. The problem is not the absence of institutions that protect creators. An institutional and international rights-management network already exists. The opportunity is interoperability: allowing evidence about identity, works, licenses, transfers and resales to travel between creators, market actors and trusted rights organizations.

AUTVIS - Associação Brasileira dos Direitos de Autores Visuais - describes itself as a non-profit collective-management association for visual artists. It states that it represents more than 50,000 Brazilian and international artists, licenses reproductions, works to secure resale rights, belongs to CISAC and represents Brazilian members in more than 25 countries through reciprocity agreements.

During the research call, AUTVIS presented its operational cycle as an "Atuação 360" flow: affiliation -> artwork registration -> monitoring / enforcement -> negotiation -> licensing -> collection -> distribution. This is important because Portable Trust should connect to an existing rights lifecycle rather than recreate it.

Field-research call with AUTVIS. Participant names and faces are blurred; the rights-management lifecycle diagram remains visible.

RESEARCH SHIFT

Do not build a new global collecting society. Build an interoperable evidence layer that can be verified and consumed by existing societies, artists, galleries, collectors and public infrastructure.

5. Identity experiment: physical persona and digital avatar

Before this buildathon proposal, the author ran an identity experiment inspired by the issuer-holder-verifier logic and field structure of Brazil's legacy RG identity document. The experiment used the author as the subject and compared two representations of the same person: the physical civil persona and a digital avatar.

A passive NFC tag was placed on the physical identity card as a physical-to-digital pointer. The experiment did not alter the legal status of the government credential and did not attempt to make the NFC tag an official identity document. It was a design probe: which facts come from a trusted issuer, which facts are held by the subject, which facts can be disclosed to a verifier, and which identifiers can remain portable across systems?

Identity design probe using a legacy Brazilian identity card and NFC. Photo, signature, document identifiers and biometric/fingerprint area are blurred for privacy.

Layer	Physical persona	Digital avatar
Primary anchor	Civil identity / institutional verification	Wallet / ENS identifier + verifiable credentials or attestations
Issuer logic	Public authority	Independent trusted issuers / attestors
Holder	Natural person carrying the credential	Natural person controlling wallet / presentation
Verification	Document and institutional checks	Cryptographic verification + issuer trust
Disclosure	Usually document-level	Potentially selective and contextual

DESIGN LESSON

Identity, representation and rights should be separable. The same person can have a civil identity, a public digital identifier and multiple independently issued credentials without any one platform owning the person's identity.

6. Research lineage: from DPP to Portable Trust

This proposal is not the first lifecycle experiment. Previous work in fashion explored the European Digital Product Passport (DPP) as a way for physical products to carry origin, supply-chain and lifecycle evidence. The current research asks what happens when the persistent object is an artwork and when the rights-holder is a creator.

Previous prototypes and production references

Reference	Link	What it tested
DPP / BaoStamp PoC	open	Product identity, lifecycle and traceability.
DPP interface evolution	open	Progression from product authentication toward a Digital Product Passport.
Ph(y)Digital Certification	open	Document evidence, IPFS and on-chain verification.
Community Token PoC	open	Community incentive primitive.
Community Token production	open	Production community / wallet layer.
NFC PoC	open	Physical-to-digital identity generator.
Art user interface	open	Production-facing artwork / creator interface.
Hub admin	open	Administrative interface for connected objects and communities.
NFT Claim PoC	open	Claim and unique digital asset primitive.
Agent Hub PoC	open	Agent orchestration primitive.
VigilAI PoC	open	AI governance and supervision experiment.

6.1 Existing certificates as a reference dataset for builders

The buildathon team can work from existing public artwork and certificate records instead of inventing every field from scratch. DigitalDubs and CryptoRastas provide concrete reference data for testing how today's application-level records could be mapped into portable claims with explicit issuers, evidence and verification rules. Treat these pages as reference records rather than a single source of truth: preserve who asserted each field, where supporting evidence lives, whether the claim can be revoked or superseded, and which parts should remain private.

Reference fixture	Existing public data	What builders can test
DigitalDubs - exhibition / collection context	Exhibition identity, gallery and place context, date, cultural narrative, artwork entry and certified-edition context.	Model EXHIBITED_AT / PRESENTED_BY / EDITION_OF context and distinguish event evidence from artwork evidence.
Build-a-box - physical fineprint + certificate	Description; 70 x 50 cm; Hahnemuhle Hemp 290gsm; edition of 50 certified copies; Ethereum record; token reference; authenticity flow; AuthorChip M40 physical link; impact framing; token / contract links.	Use as the primary physical-artwork fixture for CREATED_BY, VERIFIED_BY, PHYSICAL_LINK, TOKEN_REFERENCE, EDITION, TRANSFERRED_TO and RESOLD_FOR.
CryptoRastas - verified collection / artwork records	Unique ERC-721 works with token ID, Ethereum network, contract / metadata references, traits, work/persona context, provenance links, authenticity flow and physical-link fields.	Use as secondary fixtures to test uniqueness, collection membership, source references, issuer separation and portability across multiple artworks.

Reference URLs for the buildathon dataset

DigitalDubs: <https://art.megu.network/digitaldubs>

Build-a-box: <https://art.megu.network/cryptorastas/obra/build-a-box>

CryptoRastas: <https://art.megu.network/cryptorastas>

The continuity across these prototypes is a move from object authentication to lifecycle evidence, and now from lifecycle evidence to institutional trust and creator rights.

7. Architecture: different primitives, different responsibilities

The proposal deliberately avoids the idea that blockchain solves every layer. Each primitive has a narrower responsibility, and the new AUTVIS / CISAC research adds an important institutional layer for creator identity and rights administration.

Primitive	Responsibility
ICP-Brasil / institutional identity	Identity verification and qualified electronic signatures.
ENS	Human-readable digital identity, e.g. w3bgus.eth.
CISAC / IPI	Globally unique identification of interested parties / rightsholders and society affiliations.
EAS	Structured attestations issued by independent actors.
Verifiable Credentials	Portable attributes and claims, including selectively disclosed information.
NFT / Artwork ID	Persistent and potentially transferable digital identity for a unique artwork.
Ethereum	Public verification and programmable state for selected events.
NFC / QR	Physical-to-digital link to the artwork.
Creator CRM	Continuity of relationships with collectors, galleries, brands and institutions.
AUTVIS / ADAGP / sister societies	Collective rights management, licensing, monitoring, royalties and resale-right processes.
AI Rights Agent	Interpretation and monitoring of rights-related events; routing to human / institutional review.
Artwork / Creator Passport	Human-readable experience aggregating portable evidence.

7.1 Creator Passport + Artwork Passport

Creator Passport represents identity, credentials, representation, relationships and rights. Artwork Passport represents artwork identity, authenticity, provenance, ownership events, exhibitions, licenses, resales and related evidence.

CRITICAL DISTINCTION

Authorship != physical ownership != NFT ownership != copyright != collective-management membership.

7.2 ENS + institutional identity

A concrete digital identity reference is w3bgus.eth. ENS makes an Ethereum identity human-readable. Institutional verification can be added as an independently issued credential or attestation rather than pretending that an ENS name replaces Brazilian civil identity.

7.3 UNTP / UNECE: a standards bridge from product passports to portable lifecycle evidence

The United Nations Transparency Protocol (UNTP), developed through UNECE / UN/CEFACT, is an interoperability protocol rather than a platform. It defines interoperable credentials for product identity, conformity, traceability, facilities and identity. Its Digital Product Passport uses W3C Verifiable Credentials, while Digital Traceability Events allow independently issued lifecycle events to extend the history of an object across organizational boundaries. For Portable Trust, UNTP is a direct standards reference: the Artwork Passport can be researched as an art-specific extension or mapping of the same pattern - persistent object identity + verifiable credentials + linked lifecycle events + independent issuers - rather than as a closed proprietary passport.

Hackathon mapping: Artwork ID / physical carrier -> resolver -> Artwork Passport; creator, gallery and rights society -> credential / attestation issuers; exhibition, transfer and resale -> linked lifecycle events; authoritative institutional identity -> identity anchor. The research should document where an artwork maps cleanly to UNTP vocabulary and where creator-rights semantics require an extension.

7.4 Anti-Capture / Blockful: governance as part of the trust model

Portable Trust also needs a governance layer: decentralizing storage or verification does not by itself prevent a small set of actors from controlling schemas, issuer permissions, upgrades, revocations or dispute processes. The Anti-Capture framework and platform developed by Blockful provides a governance-security reference for identifying, assessing and mitigating governance capture risks in DAOs. The SSTM research fork/reference should be used as a framework input for asking who can change the trust rules, how concentrated that power is, and what evidence or process is required to challenge an issuer or governance decision.

Design principle: portable trust should resist both platform capture and governance capture. No single marketplace, gallery, protocol administrator or token holder should silently become the authority over authorship, provenance or creator rights.

8. Legal and institutional trust stack: Brazil, France and the global network

8.1 Berne Convention: international protection already has a protocol layer

Brazil promulgated the Berne Convention through Decree 75.699/1975. The Convention establishes an international union for the protection of authors, national-treatment principles and protection that is not conditioned on formalities. It also preserves moral rights such as authorship and integrity. Portable Trust should therefore reinforce existing international rights frameworks, not present blockchain registration as the source of copyright.

8.2 Brazilian Copyright Law: ownership and copyright are different

Law 9.610/1998 gives the author exclusive economic rights over the use of the work (Art. 28) and requires prior and express authorization for multiple forms of use (Art. 29). Article 37 states that acquiring an original work or copy does not automatically transfer the author's economic rights. Article 38 establishes the resale right over at least 5% of the verifiable increase in price in qualifying resales of original artworks or manuscripts.

8.3 AUTVIS in Brazil; ADAGP in France

AUTVIS is the Brazilian collective-management society identified in this research for visual authors. ADAGP describes itself as a French visual artists' rights-management organization. ADAGP's worldwide network page lists almost fifty sister societies and explicitly lists AUTVIS for Brazil; ADAGP says this network allows it to represent more than 200,000 artists worldwide. AUTVIS separately states that it is a CISAC member and operates reciprocal representation in more than 25 countries.

KEY IMPLICATION

The global graph of trusted rights organizations already exists. A Portable Trust protocol can focus on interoperable credentials, artwork events and verifiable evidence that these organizations can issue, receive or validate.

8.4 IPI: an existing global identity primitive for rightsholders

The CISAC Interested Party Information (IPI) system is designed to uniquely identify natural persons or legal entities that hold an interest in an artistic work, across categories of works, roles and corresponding rights. CISAC describes IPI as an essential component of data exchange between member societies. This is a stronger precedent than inventing a new creator identifier from zero.

Research direction: investigate how IPI / society identity, civil or qualified identity, ENS / wallet identity and artwork-level credentials can interoperate while keeping each issuer's authority and scope explicit.

9. Where LabSEC can shine

9.1 Ethereum Attestation Service

Not every important fact about an artwork is ownership. Much of the lifecycle consists of claims: CREATED_BY, VERIFIED_BY, EXHIBITED_AT, REPRESENTED_BY, LICENSED_BY, TRANSFERRED_TO, RESOLD_FOR. EAS provides schemas for structured attestations and can support on-chain or off-chain attestations and revocation depending on the schema.

TRUST MODEL

The platform does not own the truth. It makes independently issued evidence understandable and verifiable.

9.2 The hard problem is issuer trust

The difficult problem is not writing data to Ethereum. It is deciding what makes an attestation trustworthy. The core questions are:

- Who is the issuer and how was the issuer identified?
- Who is authorized to issue which type of claim?
- How is each claim signed, timestamped and linked to evidence?
- How are revocation, supersession and compromised keys handled?
- What data stays private, what is selectively disclosed and what can be public?
- How do independent institutions recognize one another?
- How can a rights society such as AUTVIS attach or verify creator / representation / licensing claims without becoming dependent on the application that displays them?

This is a PKI, digital-signature, credential, authentication, authorization, revocation, privacy and interoperability problem. Ethereum provides verification primitives; trust architecture makes them institutionally meaningful.

9.3 Suggested trust roles for the PoC

Actor	Example claim	Trust question
Artist	CREATED_BY / SIGNED_BY	How is the artist identity bound to the signing key?
Gallery	VERIFIED_BY / EXHIBITED_AT	Is this gallery authorized and can its credential be revoked?
Collector	TRANSFER_ACCEPTED	How are both parties authenticated without publishing unnecessary identity data?
Rights society	REPRESENTED_BY / RIGHTS_CONTACT	How is membership / representation status expressed and kept current?
Market actor	RESOLD_FOR	Who may attest transaction price and what evidence is retained?

10. Hackathon PoC options to validate with AUTVIS

The same trust infrastructure can validate different creator-economy pain points. The updated proposal prioritizes a journey that demonstrates independent issuers and a real economic consequence.

Recommended demo fixture: Build-a-box from the DigitalDubs fineprint series. Its public record already combines a physical edition, material and dimensions, Ethereum/token references, an authenticity certificate flow and an AuthorChip physical link. CryptoRastas records can be used as additional fixtures to test the same schema across unique ERC-721 works and multiple artwork identities.

Focus	Problem	PoC	LabSEC challenge
A. Authenticity	Certificates and provenance become fragmented.	Artist signs authorship; gallery independently verifies; EAS stores / verifies attestations; NFC opens Artwork Passport.	Identity + signature + issuer trust.
B. Ownership transfer	Continuity is lost after the first sale.	Collector A initiates transfer; Collector B accepts; provenance remains intact.	Authentication of parties + transfer integrity.
C. Resale rights	Artist may not see secondary-market transactions.	Resale attestation + AI Rights Agent flags a potential direito de sequência event and routes it for rights review.	Transaction evidence + trusted issuers + privacy.
D. Collective-rights link	Representation / licensing status can be disconnected from artwork evidence.	Rights society issues or verifies REPRESENTED_BY / RIGHTS_CONTACT credential.	Institutional identity + authorization + revocation.
E. AI Rights Agent	Artists may underprice commercial licensing.	Upload contract; AI structures territory, duration, media, derivatives and usage rights.	Document provenance + access control + auditability.

RECOMMENDED POC

A + B + C + a minimal rights-society credential: AUTHENTICITY -> TRANSFER -> RESALE EVENT. Authentication creates trust; transfer demonstrates lifecycle continuity; resale creates a concrete creator-rights consequence; an institutional credential shows how the system connects to the existing rights network.

Primary validation question for AUTVIS: where in the artwork lifecycle is the greatest amount of creator value, information or rights currently lost because evidence does not travel with the artwork or creator?

11. The three-minute demo

A visitor taps the NFC / AuthorChip on a physical artwork - preferably the Build-a-box reference fixture - and the Artwork Passport opens a compact chain of independently verifiable evidence. The demo may seed its interface with public DigitalDubs / CryptoRastas certificate data while making the issuer and evidence source of every claim explicit.

View	Demo state
Creator	w3bgus.eth / digital avatar; institutional identity verification represented separately.
Rights identity	Optional IPI / collective-rights identifier or society representation credential where available.
Authenticity	Artist authorship attestation + independent gallery verification.
Provenance	2026 created -> 2026 authenticated -> 2027 Collector A -> 2029 Collector B.
Current state	Physical owner: Collector B creator remains the author copyright status shown separately.
Rights society	REPRESENTED_BY / RIGHTS_CONTACT attestation points to the relevant collective-management organization.
AI Rights Agent	Resale detected. Potential Artist's Resale Right event. Review jurisdiction, transaction evidence and collective-rights process.

ONE PHYSICAL ARTWORK

Identity + signature + attestations + artwork ID + NFC + public verification + institutional rights network + AI-assisted rights interpretation.

11.1 Minimal technical path

- Create an Artwork ID and an Artwork Passport web view.
- Bind the artwork to an NFC or QR pointer.
- Create schemas for CREATED_BY, VERIFIED_BY, TRANSFERRED_TO, RESOLD_FOR and REPRESENTED_BY.
- Use test wallets and EAS-compatible attestations; keep sensitive personal data off-chain.
- Make issuer identity and revocation status visible in the UI.
- Use a simple AI layer only to interpret a resale / licensing context and explain next steps; avoid automated legal determination.
- Demo the same evidence in a second interface or verifier to prove portability beyond one application.

Success is not "everything on-chain". Success is one credible event chain that remains verifiable when the frontend changes.

12. Public-infrastructure opportunity

12.1 ICP-Brasil

The Instituto Nacional de Tecnologia da Informação describes an ICP-Brasil digital certificate as a digital identity that securely identifies people, legal entities, systems, applications or equipment and enables qualified electronic signatures. It binds verified identity to cryptographic keys, offering a bridge between legal / institutional identity and public digital identifiers.

12.2 Gov.br and the existing public artwork-registration service

Brazil already offers a federal service through Gov.br to register or amend copyright records at the Fundação Biblioteca Nacional. The service records legal information about a work, preserves a copy, issues an official certificate and supports amendments, including rights-related changes. The research therefore should not claim that Brazil needs an artwork registry; it should ask how existing registration can interoperate with machine-verifiable lifecycle credentials.

12.3 EUDI as an emerging interoperability reference

Regulation (EU) 2024/1183 establishes the European Digital Identity Framework and European Digital Identity Wallets. The relevant pattern is ISSUER -> HOLDER / WALLET -> VERIFIER: identity and attestations can be presented across institutional boundaries rather than remaining locked inside one provider's database.

REGULATORY PROGRESSION

DPP: products carry lifecycle information. EUDI: people carry identity and attributes. IPI / CISAC: rightsholders carry interoperable identity across societies. Portable Trust: people and objects carry verifiable evidence across institutions and market actors.

12.4 A possible future service: Creator / Artwork Passport

A creator authenticates through trusted infrastructure, links a public digital identifier, registers an artwork where appropriate, signs authorship, and receives or presents machine-verifiable credentials. Galleries, museums and rights organizations add independent attestations. Transfers and resales extend provenance while sensitive documents remain off-chain. The wallet and passport become presentation layers; authority remains distributed among the relevant issuers.

13. Beyond art: innovation hubs

Art is the hackathon use case. The same trust architecture can later address another portability problem: professionals build years of participation, mentorship, education, projects and reputation inside one innovation ecosystem and often start from zero when they move to another hub or city.

Context	Journey	Portable evidence
Creative economy	Artist -> Gallery A -> Creator / Artwork Passport -> Gallery B -> Collector -> rights society	Authorship + provenance + rights + relationships + representation
Innovation ecosystems	Talent -> Hub Uberlândia -> Community Passport -> Hub Florianópolis -> University / Company	Membership + education + participation + contribution + reputation

SAME ARCHITECTURE

ISSUER -> CREDENTIAL / ATTESTATION -> HOLDER -> VERIFIER

13.1 What the art use case teaches the hub use case

- A credential should state who issued it, under which authority and for what scope.
- Reputation is not one global score; it is a set of contextual claims from independent issuers.
- Portability means a verifier can understand evidence without asking the original platform for permission.
- Privacy requires separating public proof from private supporting documents.
- Revocation and supersession matter as much as issuance.
- Physical touchpoints such as NFC can open the experience, while trust comes from signatures and issuer governance.

This keeps the larger MEGU / passport opportunity grounded in the same research principle rather than turning art into an isolated prototype.

14. Research question

QUESTION

Can a physical artwork carry a verifiable lifecycle of authorship, provenance, transfers and rights, with claims issued by independent actors, without depending on a single platform as the authority?

The AUTVIS research adds a second question: can this portable evidence interoperate with the collective-rights institutions and international identifiers that already protect creators, instead of creating a parallel rights system?

14.1 Validation split

Partner / layer	What it validates
AUTVIS / rights-management domain	Where creator value and rights information are lost; which events matter operationally; which credentials a society could issue or consume.
LabSEC	Identity, signatures, PKI, credential trust, authorization, revocation, privacy and interoperability.
Ethereum / EAS	Public verification, persistent schemas and independently verifiable attestations.
AI Rights Agent	Human-readable interpretation of contracts / resale contexts and routing to institutional or legal review.
NFC / Artwork Passport	Physical-to-digital interaction and a usable presentation of the evidence graph.

If one artwork can demonstrate this end to end, the project proves a portable trust pattern that can be reused for creators, products, communities and innovation hubs. UNTP provides a standards reference for interoperable object identity and lifecycle credentials; Anti-Capture adds the governance question of how the rules and issuer powers remain resistant to capture.

BUILDATHON PRINCIPLE

One artwork. Several issuers. One portable evidence chain. No single application owns the truth.
